Make It Do Something

PF-04 portfolio feature submission

Azizul Abedin Azmi

THE ONE FEATURE

My portfolio has exactly one dynamic feature: a working contact form. A visitor can enter a name, email address, and message on the live site. Netlify Forms receives and stores the submission in the Netlify dashboard, so I do not need to build or pay for a separate server.

Feature	Contact form with Netlify Forms
Live site	https://azizulabedinazmi.netlify.app/
Hosting tier	Netlify free tier
Form name	`contact`
Source	https://github.com/azizulabedinazmi/FlyRank_PF-04

WHAT A BACKEND IS

A backend is the part of an application that runs away from the visitor's browser. It receives requests, validates or processes data, stores data, and returns a result. The browser shows the interface, but the backend is what makes a feature persist or perform work after the page is loaded.

For this project, I did not write a custom backend. Netlify provides the backend service through Netlify Forms. This is useful because the portfolio is static, but the contact form still needs somewhere reliable to send and store messages.

HOW THE DATA FLOWS

1. A visitor opens the portfolio over HTTPS and fills in the contact form.
2. The form has the name `contact` and the `netlify` attribute. The hidden `form-name` field identifies the form.
3. The browser sends the form fields to Netlify when the visitor presses "Send message". Required fields prevent an empty name, invalid email, or empty message from being submitted.
4. Netlify receives the request, matches it to the detected `contact` form, and stores the submission in the Forms dashboard.
5. I can review the message in Netlify and reply using the visitor's submitted email address.

```
<form name="contact" method="POST" netlify
      netlify-honeypot="bot-field">
  <input type="hidden" name="form-name" value="contact">
  <input type="text" name="name" required>
  <input type="email" name="email" required>
  <textarea name="message" required></textarea>
</form>
```

WHY THIS MEETS THE BRIEF

- **Exactly one feature:** the contact form is the only server-backed feature on the portfolio.
- **Free tier:** the site and form are hosted by Netlify without a paid server or database.
- **End to end:** the form is deployed at the live URL and Netlify Form detection is enabled for the site.
- **Understanding:** the data flow is explained in plain words above rather than treating the service as a black box.

EVIDENCE OF THE REAL TEST

[TODO: Insert a screenshot showing the submitted test message in Netlify Forms, and optionally the confirmation page or notification email.]

Test details to record:

Test URL	`https://azizulabedinazmi.netlify.app/`
Test date	**[TODO: Add date]**
Test name	**[TODO: Add the name used]**
Result	**[TODO: Confirm the submission appears in Netlify Forms]**

REFLECTION

NOTES

- **What changed in the prompt:** I changed the form from a custom redirect and custom JavaScript submission flow to Netlify's documented native `netlify` form pattern.
- **What improved in the output:** The implementation is smaller and uses the platform's built-in form detection, submission handling, and dashboard storage.
- **What still failed:** The repository cannot prove that a real visitor submission reached the dashboard; that requires one final manual test in Netlify.
- **What I would try next:** Submit a test message, capture the dashboard entry, and add that screenshot to this report before uploading it.
